

Parking lot USB exercise

Contents	The USB drive contains personal information such as family and pet photos, along with documents that may contain personally identifiable information (PII). It also stores sensitive work-related files, including a new hire letter, employee shift schedules, a resume, a budget tracker, and wedding planning materials, creating risks when personal and business data are stored together.
Attacker mindset	An attacker could use the personal information to target Jorge or people connected to him through phishing, social engineering, or identity-based attacks. The work files could reveal employee, scheduling, hiring, and financial information that might help an attacker impersonate staff, target other employees or relatives, or develop a path toward unauthorized access to hospital systems.
Risk analysis	Technical controls should block unauthorized USB devices, scan removable media for malware, and use endpoint protection to detect malicious files or code. Operational controls should require employees to avoid plugging in unknown USB drives and to report found devices to IT or security personnel. Managerial controls should establish clear removable-media policies, provide regular security awareness training, and keep personal and business data on separate storage devices.
